

# Design Motivation

Humans in the USA consume ~4 quadrillion BTUs of thermal energy per year heating spaces

Humans in the USA produce ~5 **quintillion** BTUs of thermal energy a year with their **bodies**.

BUT: mediating microclimate is not straightforward. (Focus of current NSF Cyber-Physical Systems grant.)

# Next Steps: Closing the Loop

Thesis - it is possible to achieve operational carbon and energy savings through on-body heating, by replacing or reducing space conditioning energy.

Communication between on-body and building heating systems

Controlling smart buildings: inputs and efficiency models

## Skill & Knowledge Areas

### Comfort measurements & ASHRAE 55

- Operative + MRT temperatures
- Activity, metabolic rates, clo levels
- Measure & predict impact of on-body systems

### Wearable Tech

- On-body heating devices
- Cooling devices possible? – Peltier Effect on-body cooling
- Appropriate designs for different activities/environments
- Engineering & fabrication

### Building Design & Energy

- Enclosure design and heating/cooling load predictions
- Air temperature setpoints and surface temps
- Mechanical systems & controls
- Energy modeling to estimate energy savings & carbon impact

# Wearable System Development

Thermal Chamber Test - Heated Glove Condition

# Modeling Deployment Scenarios

## Use energy modeling to determine potential for energy/carbon savings

### Garment/Social Factors

- 1) Thermal capability (capacity for temperature differential)
- 2) Heat output (IGs to space)
- 3) Energy consumption
- 4) Controls/coordination with mechanical system
- 5) User acceptance (where it can/will be worn)

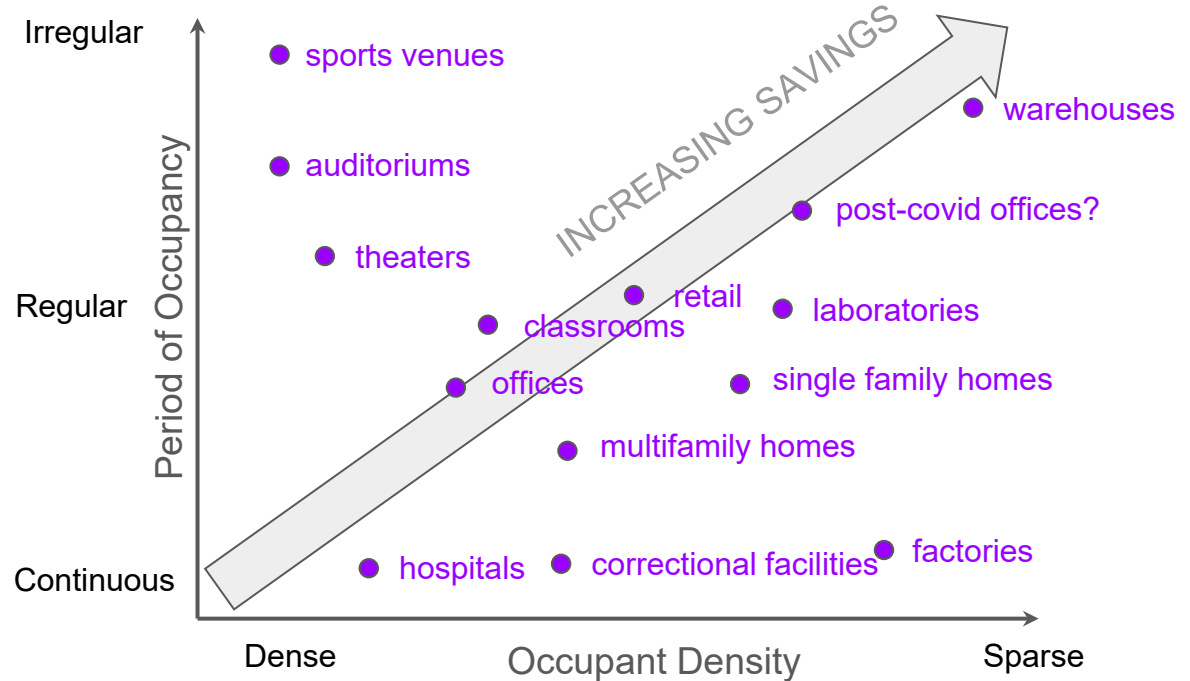

### Building Factors

- 1) Climate zone (cold, mixed, etc)
- 2) Building geometry, enclosure, and type
- 3) Heat load of space/building - internal dominated (more cooling) vs. enclosure dominated (more heating)
- 4) Capacity, and efficiency of mechanical system
- 5) Occupant density, schedule, and internal gains

# Modeling Deployment Scenarios

Different space/occupancy types offer different energy/carbon savings potentials.

Sparse and irregularly occupied spaces may use a lot of space- heating energy for little benefit. They could offer the best opportunity for energy/carbon savings.

# Modeling Deployment Scenarios

## Warehouse, pre-80's

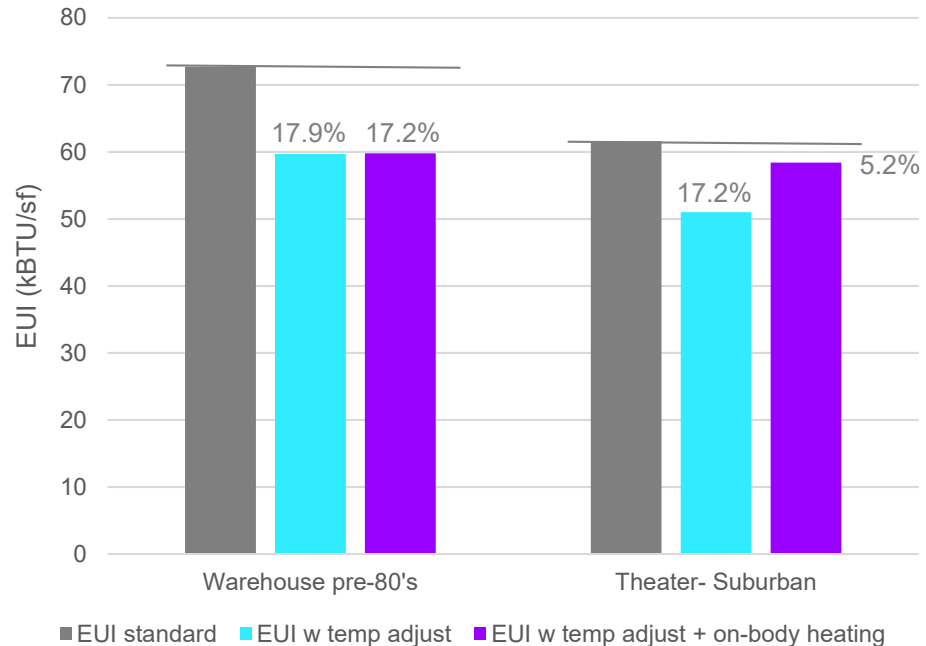

- Poor thermal envelope
- Large volume of interior space to condition
- Sparse occupancy

## Large, suburban theater

- Average thermal envelope
- Large volume of interior space to condition
- Higher occupancy

Assume on-body heating consumes 100W/person

Energy Consumption & Savings Percentage

# Research Questions

- 1) **Thermal garment design** - which textiles, heating elements, element placement, garment type, and user interfaces are best?
- 2) **Effectiveness** - What is the reduction in air temperature that can be achieved with on-body heating in different occupancies while maintaining comfort for all users?
- 3) **Energy and carbon impacts** - What energy and carbon savings are possible for different occupancy/building types?
- 4) **Control systems** - What are the impacts of control systems (the interaction between the building mechanical system and on-body heating systems)?
- 5) **Building Implications** - What are the thermal envelope and mechanical system changes that can optimize the function and energy savings of these garments?

# Target Outcomes: Collaborative Research Grant

High priority grants:

- 1) NSF Cyber-Physical Systems
- 2) NSF Smart and Connected Cities

Lower priority grants:

- 1) NSF Convergence Grant
- 2) AIA Upjohn Research Initiative
- 3) Department of Energy grants (?)
